## Canonical correlation analysis by utilizing suit able software

Look at the data described in Exercise 10.16 of Johnson, Wichern. You may find it in the file P10-16.DAT. The data for 46 patients are summarized in a covariance matrix, which will be analyzed in R. Read through the description of the different R packages and functions so you may chose the must suitable one for the analysis. Supplement with own code where necessary.

The given matrix is the following:

V1	V2	V3	V4	V5
1106.000	396.700	108.400	0.787	26.230
396.700	2382.000	1143.000	-0.214	-23.960
108.400	1143.000	2136.000	2.189	-20.840
0.787	-0.214	2.189	0.016	0.216
26.230	-23.960	-20.840	0.216	70.560

Thus, separating the variance-covariance matrix it is obtained that

$$\Sigma_{11} =$$

V1	V2	V3
1106.0	396.7	108.4
396.7	2382.0	1143.0
108.4	1143.0	2136.0

$$\Sigma_{22} =$$

	V4	V5
4	0.016	0.216
5	0.216	70.560

$$\Sigma_{21} =$$

	V1	V2	V3
$\overline{4}$	0.787	-0.214	2.189
5	26.230	-23.960	-20.840

$$\Sigma_{12} =$$

V4	V5
0.787	26.23
-0.214	-23.96
2.189	-20.84

It can be computed that

$$M = S_{11}^{-1/2} S_{12} S_{22}^{-1} S_{21} S_{11}^{-1/2} =$$

0.0468068	-0.0374259	0.0813854
-0.0374259	0.0306007	-0.0716743
0.0813854	-0.0716743	0.2059907

Its eigen-decomposition is given by

The first two eigenvalues  $\overrightarrow{\alpha}$ :

The first two eigenvectors  $\overrightarrow{e}$ :

0.3749438	0.7634104
-0.3220478	-0.4247428
0.8693114	-0.4866191

Also,

$$D = S_{22}^{-1/2} S_{21} S_{11}^{-1} S_{12} S_{22}^{-1/2} =$$

0.2671702	0.0109346
0.0109346	0.0162279

Its eigen-decomposition is given by

Eigenvalues  $\overrightarrow{\beta}$ :

 $\frac{x}{0.2676458}$ 0.0157523

Eigenvectors  $\overrightarrow{f}$ :

-0.9990556	0.0434508
-0.0434508	-0.9990556

It is defined that

$$\hat{\mathbf{a}}'_k = \hat{\mathbf{e}}'_k S_{11}^{-1/2}$$
  
 $\hat{\mathbf{b}}'_k = \hat{\mathbf{f}}'_k S_{22}^{-1/2}$ 

Thus, based in results above:

 $\hat{\mathbf{a}} =$ 

0.0131007	0.0247525
-0.0144383	-0.0093175
0.0233997	-0.0086672

$$\hat{\mathbf{b}} =$$

-8.0655751	0.3751678
0.0191591	-0.1200675

M and D have the same eigenvalues, so the canonical correlations can be calculated from one of

$$[\hat{\rho_1^*},\hat{\rho_2^*}] =$$

 $0.5173449 \quad 0.1255082$ 

a) Test at the 5% level if there is any association between the groups of variables.

$$H_0: \Sigma_{12} = 0$$

$$H1: \Sigma 12 \neq 0$$

We have  $p \cdot q = 3 * 2 = 6$  degrees of freedom. For n = 46, we use Bartletts approximation and our test statistic is:

$$-\left(n-1-\frac{1}{2}(p+q+1)\right)\ln\prod_{i=1}^{2}\left(1-\hat{\rho_{i}^{*2}}\right)$$

3

For the obtained canonical correlations it is obtained that

$$test_1 = 13.74948$$

$$test_2 = 0.6668632$$

It is seen that  $test_1 > 12.59159$ , thus according to  $test_1 H_0$  should be rejected. Now,  $test_2 < 12.59159$ , then according to  $test_2$  we fail to reject  $H_0$ .

In summary we conclude that we cannot assume that

$$H_0: \Sigma_{12} = 0$$

at a significance level  $\alpha = 0.05$ 

b) How many pairs of canonical variates are significant?

$$H_0: \rho_2 \neq 0$$

and

$$H_1: \rho_2 = 0$$

At  $\alpha = 0.05$  significance, we get a test statistic of 0.66, smaller than the critical value of 12.59. We then reject  $H_0$ , meaning only the first canonical correlation ( $\rho_1$ ) is significantly different from 0.

c) Interpret the "significant" squared canonical correlations. Tip: Read section "Canonical Correlations as Generalizations of Other Correlation Coefficients".

The significant squared canonical correlation  $(\rho_1^2)$  measures the overlap between  $X^{(1)}$  and  $X^{(2)}$ , the different group of variables.

d) Interpret the canonical variates by using the coefficients and suitable correlations.

The canonical correlations variables are:

$$U_1 = 0.0131007X_1^{(1)} - 0.0144383X_2^{(1)} + 0.0233997X_3^{(1)}$$
$$V_1 = -8.0655751X_1^{(2)} + 0.0191591X_2^{(2)}$$

We can interpret  $U_1$  as a measure of how well a patient can process sugar (glucose) in their bloodstream.  $V_1$ , on the other hand, can be interpreted as how prone the patient is to diabetes.

e) Are the "significant" canonical variates good summary measures of the respective data sets? Tip: Read section "Proportions of Explained Sample Variance".

## [1] "The explained variance"

The correlation variate explains 44% of the total sample variance. We conclude therefore that the significant canonical variates are not a good summary because there might be nonlinear relations.

f) Give your opinion on the success of this canonical correlation analysis.

While the canonical correlation variables have insightful interpretration, the analysis is not good enough given the small summary capability of its variates.
